Acknowledgements

We would like to thank our supervisors Jens Walther and Robert Mikkelsen, who allowed us to work on a project we hold very dear. The project let us perform incredibly well for a first time racer at the Formula Student competition in Silverstone, and the Vermilion Racing team will hopefully live on many years ahead.

Furthermore, a big thanks to Rasmus Himborg from Philips Lighting Denmark, for helping us machine the 1/4 scale wing used in the windtunnel tests.

Introduction

Vermilion Racing is a newly started Electric race car team building their first vehicle: The Eevee [1]. The teams' purpose is competing against other Universities at the Silverstone race track from the 11th to the 16th. As members of the team, the purpose of this report is to document the design process of the rear wing of the first car, the Eevee, and provide an aerodynamic package documenting drag and downforce.

Aerodynamics is a major decider in racing today. Cornering, not top speed is the deciding factor amongst the teams, and aerodynamics is the key. Drag, lift and side force are the three cornerstones to vehicle aerodynamics. A car's ability to handle depends on the grip of the tyres, and downforce directly increases grip by increasing the downwards load on the tyres without adding a weight penalty. Additionally, drag directly decreases the speed of a vehicle by increasing air resistance, but is of less importance as the car's in this class have far more accelerative power than the tyres can handle [2]. Designing the bodyworks of Eevee is therefore a dance of downforce.

This bachelor thesis attempts to lay down the ground work for designing, optimizing and manufacturing the car's rear wing. Our advisor, Jens Honore Walther, proposed simulating the wing geometry in order to both cheapen and quicken the optimization process, but also gain insight into how flow in front of the rear wing affects lift performance. The purpose of the numerical simulations are ultimately to create an easily producable wing in a very short timespan, that produces ample amounts of negative lift for the time spent in production.

As this is the first year the team building a car, time and money for pro-

FIXme Note: write about what has been done prior

duction is sparse. To ensure the simulated optimizations are true, a wind tunnel test is performed on a down-scaled wing using Flow Similarity theory. The measurements are compared with the results from a computational fluid dynamics simulation performed in Star-CCM+ to verify the preciseness of the simulations. Based on this, the size, x - and y -distance between the multi-element wings, angle of attack and height relative to the chassis is then optimized for maximum downforce. The multi-element wing is taken from theoretical abstraction to reality with a physical design of the wing. The position, deflection and dimensions of the wing is thoroughly described by the rules of the Formula Student competition, guiding the final design process. In the final chapter, theories regarding strength of sandwich structured composites and carbon fiber molding are handled, in order to describe the production choices made. Finally, the end result is discussed and possible improvements to the wing and mounting system is listed.

Measurements and tests have been carried out at the DTU Wind laboratory's Red wind tunnel with the help of our supervisor Robert Flemming Mikkelsen the 19th of June.

The entire project is publicly available on https://github.com/carlegroen/bachelor_project_racecar_aero, where all work files, data, various notes and CAD drawings can be found. The Formula Student team at DTU: Vermilion Racing can be followed on fb.com/FSDTU.

1.1 Design Philosophy

Designing a car with hundreds, if not thousands different factors is incredibly difficult. Therefore, analyzing which things matters and which don't is crucial to the teams' success. First, the deadline for finishing the wing is soon. This sets a limit on the complexity of the wing's dimensions. Secondly, this is the first iteration of the car, thus no decision can be based on prior experience, and optimization has to wait for the next iteration. Finally, the finances of the car is tight. This forces us to go with a low-cost solution. We therefore have to go for a simple, low cost wing, basing the design solely on literature and experience other teams have done.

The wing has to have as low weight as possible, in order to ensure optimum acceleration of the car. Thereto, drag has to be kept low, but the effect from drag is near negligible, which will be explained in section 2.1. Lastly, we have to maximize the downforce provided by the wing, but also ensure that the center of pressure is kept as constant as possible. If the frontwing, undertray and rear wing's downforce don't scale equally with speed, the

1.1. Design Philosophy

center of pressure will move during acceleration. This will make the car's handling unpredictable, and potentially limit the driver's confidence in the car.

2

Aerodynamic Effects on Vehicle Performance

The first argument to the importance of aerodynamics is based around two facts: The fact that drag is negligible in regards to the Formula Student vehicle's top speed on straights, and the fact that aerodynamically increasing the vehicle's *effective* mass due to downforce increases tyre grip, which in turn allows for higher cornering velocities.

The second part of this chapter covers the importance of centering the effective mass increase due to aerodynamic devices close to the center of gravity – otherwise handling characteristics becomes a function of velocity.

2.1 Drag Effects on Straights

First, let's explain what makes a car fast, and what parameters we can change to improve the speed of our car.. The car's acceleration can be described by Newton's second law as:

$$\sum F_x = m\ddot{x} = F \quad (2.1)$$

FiXme Note: introduce a figure with drag and lift to show what's going on

FiXme Note: stort D eller lille d i ligningen?

Where the sum of forces in the x-direction (the direction of travel) can be expressed as the force already pertained by the vehicle, minus the drag force:

$$F - C_D \left(\frac{1}{2} \rho \dot{x}^2 A \right) = m\ddot{x} \quad (2.2)$$

2.1. Drag Effects on Straights

Figure 2.1: Frontal area of the car with a dummy wing inserted into the CAD model, in order to get an estimate of the drag coefficient C_D .

Where C_D is the drag coefficient of the vehicle, ρ is the density of the fluid it moves in and A is frontal area of the vehicle. Assuming we're moving at a steady speed, the acceleration is 0, hence

$$F = C_D \left(\frac{1}{2} \rho \dot{x}^2 A \right) \quad (2.3)$$

As we were interested in the speed of the car, let's solve for the velocity. The force is given by $F = \frac{P}{\dot{x}}$, where P is the power of the car, which gives:

$$\dot{x} = \left(\frac{2P}{C_D (\rho A)} \right)^{\frac{1}{3}} \quad (2.4)$$

This is assuming we're traveling at terminal velocity – that is, the point where the Driving Force = Friction Force. The terminal velocity of the racer is then easily calculated, as the competition restricts the maximum amount of power to 80 kW, and the frontal area of the car is approximated from the CAD drawing seen in figure 2.1.

Fixme Note: fix calculation to use 0.99 instead of 1.2
Fixme Note: missing radiators

$$\dot{x}_{\max} = \left(\frac{2 \cdot 80 \text{ kW}}{0.85 (1.225 \text{ kg m}^{-3} 1.2 \text{ m}^2)} \right)^{\frac{1}{3}} = 50 \text{ m s}^{-1} = 181.4 \text{ km h}^{-1} \quad (2.5)$$

however, given the ruleset a forecasted maximum of 110 km h^{-1} allows a much larger drag coefficient C_D :

$$C_D = \frac{2P}{\dot{x}^3 (\rho A)} = \frac{2 \cdot 80 \text{ kW}}{(120 \text{ km h}^{-1})^3 (1.225 \text{ kg m}^{-3} 1.2 \text{ m}^2)} = 2.82 \quad (2.6)$$

Thus, the car's top speed will only be limited by a drag factor > 2.82 , insert source which is far above the drag introduced by the aerodynamic devices.

From this derivation, it is clear that the car's abilities at maximum speeds far exceed the requirement of the track. Therefore, the next step is to

improve cornering speeds which depend strongly on the tyre's grip on the surface of the road [2].

2.1.1 Downforce Effects on Cornering

Shown before, drag does not limit the car's performance on straights. During cornering, drag is not an issue either, but the grip of the tyres limits the maximum velocity before the vehicle loses traction due to the centripetal force which is given by: [3]

$$F_{\text{centripetal}} = \frac{m\dot{x}^2}{r} \quad (2.7)$$

where r is the distance to the center of the cornering circle. The frictional force the car exerts due to downforce and tyre grip is given by:

$$F_{\text{friction}} = \mu F_{\text{normal}} \quad (2.8)$$

where the normal force is given by both the weight and (negative) lift of the car, which serves as an effective mass increase:

$$F_{\text{friction}} = \mu \left(mg + \frac{1}{2} \rho C_L A \dot{x}^2 \right) \quad (2.9)$$

The vehicle will lose traction when the frictional force is less than the centripetal force.

$$\frac{m\dot{x}^2}{r} > \mu \left(mg + \frac{1}{2} \rho C_L A \dot{x}^2 \right) \quad (2.10)$$

Giving the maximum velocity for a given corner radius before the car skids out:

$$\Rightarrow \dot{x} < \left(\frac{2\mu m g r}{m - \mu C_L \rho r A} \right)^{\frac{1}{2}} \quad (2.11)$$

Again, the forecasted variation in radii of corners is prescribed by the rules to be between 3 m to 50 m [4]. Plotting this for various C_L values between 1.5 to 2.6 [5], assuming $m = 300 \text{ kg}$, $\mu = 1.5$ [6] and $A = 0.99 \text{ m}^2$ as previously used. The result can be seen in figure 2.2.

2.1.2 Load Distribution

The scope of this thesis is not to incorporate a full aerodynamic package, but a quick overview of load distribution is essential to understanding the behaviour of the car.

The effective mass added from negative lift depends on the lift coefficient. It is evident that different items on the car carry different lift coefficients,

2.1. Drag Effects on Straights

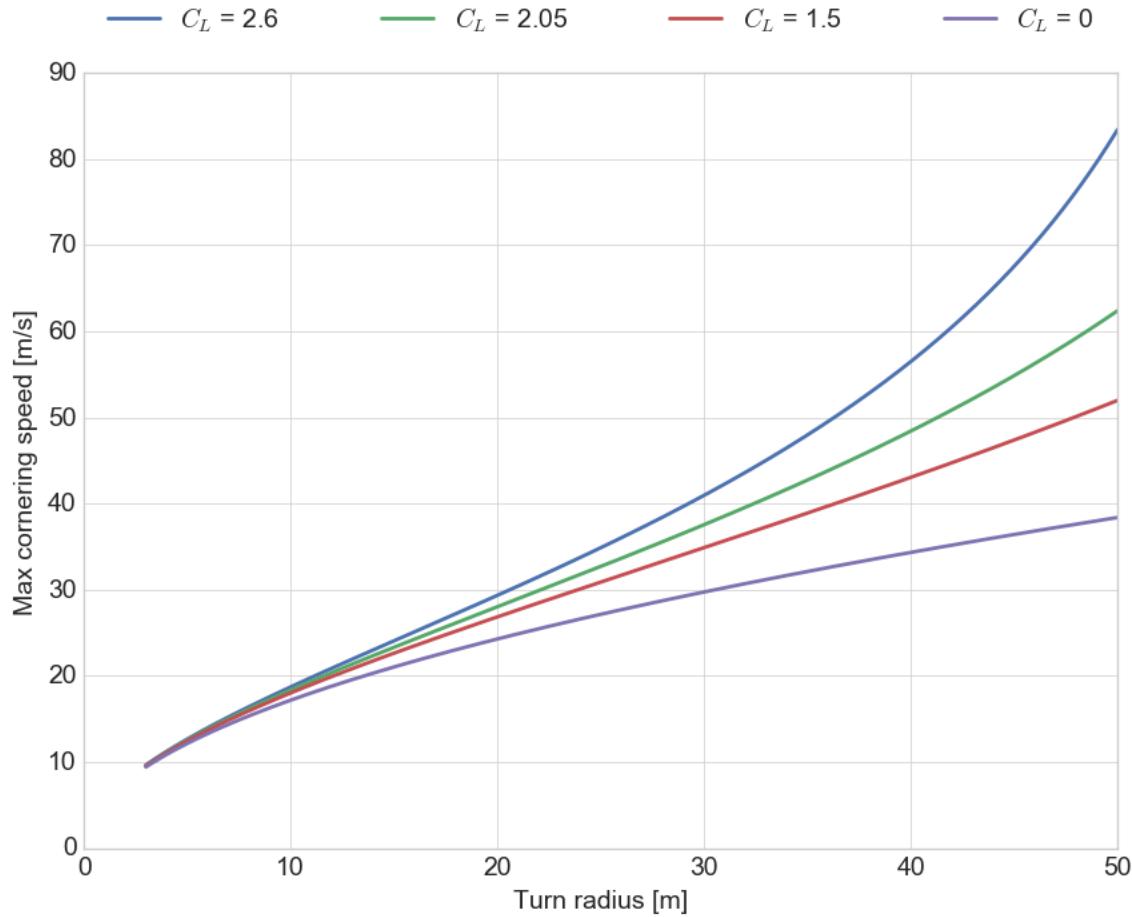

Figure 2.2: Cornering speed as a function of turn radius for various lift coefficients.

thus making the lifting forces over the cars length a function of relative speed. For the unexperienced driver, this is not easily managed as handling characteristics change with velocity. Therefore, it is desirable to have the aerodynamic center of pressure close to the car's center of gravity, in order to have similar handling at all velocities. While this is not handled in this thesis, it is ideal for future iterations and essential for a full aerodynamical package.

3

Airfoils and Inverted Wings

Achieving a large negative lift coefficient C_L can be done in many ways. Inspecting race cars throughout the years show that airfoils have been used as early as 1966 when Jim Hall attached a rear wing to his Chaparral 2E [7]. Since then, the inverted wings have been a staple in the racing industry with various three dimensional geometries affecting the overall performance even further.

This chapter covers the pressure distribution of various airfoils, the selection criterions of the competition, three dimensional geometrical effects and the tools of the optimization trade.

3.1 Airfoil theory

An airfoils is the 2-dimensional cross section of a wing, that's characteristic of the wing's lifting characteristics. It is important to know the nomenclature: The leading edge is the most forward point of the wing, the trailing edge is the most rearward point of the wing. Camber is how much the wing "flexes".

Theory of airfoils from katz book, to be written tuesday 19.

Also from katz book to be written tuesday 19.

Building physical models is cool, wind tunnel time is expensive though
Let's use CFD!

To make sure CFD works, we need to perform experiments to verify simulations work.

Let's make a small scale wind tunnel test and simulate the rest!

4

Wind Tunnel Experiment

Verifying the simulated aerodynamic effects is crucial to ensuring the correctness of the numerical analysis. In order to assess the reliability of the previously conducted simulations, a physical measurement of the pressure along the down-scaled wing will provide results for comparison.

FIXme Note: sounds awful.
fix

Measurements and tests have been carried out at the DTU Wind laboratory's Red wind tunnel with the help of our supervisor Robert Flemming Mikkelsen the 19th of June.

4.1 Aerodynamical Theory

The theories explaining how fluid effects scale between varying wing sizes is explained, in order to justify using a down-scaled model as evaluation to a real size wing.

4.1.1 Similarity of Flows

In order to perform tests on the rear wing, it has to be scaled down to fit inside the wind tunnel. This reduces the physical size of the wing, which under equal circumstances changes the flow around it. In order to correctly emulate the simulated flow inside a wind tunnel, the Reynolds number and Euler number have to be the same, assuming incompressible flows:

$$Re_m = Re \quad (4.1)$$

$$Eu_m = Eu \quad (4.2)$$

Mathematically, the Reynolds- and Euler number are defined as:

$$Eu = \frac{p_u - p_d}{pv^2} \quad (4.3)$$

where v is the characteristic velocity of the flow, p_u denotes upstream pressure, and p_d denotes downstream pressure, and:

$$\text{Re} = \frac{uL}{\nu} \quad (4.4)$$

where u is the velocity relative to the object, L is the characteristic length and ν is the kinematic viscosity of the fluid.

For a down-scaled model, matching Reynolds- and Euler number requires an increase in velocity, inversely proportional to the increase in length

Fixme Note: skriv det her ud plx.

$$\begin{aligned} \frac{u_m L_m}{\nu} &= \frac{uL}{\nu} \\ \Rightarrow u_m &= \frac{L}{L_m} u \end{aligned} \quad (4.5)$$

Given the nature of the competition, the average cornering speeds are around $55 \text{ km h}^{-1} = 15.28 \text{ m s}^{-1}$, which is where downforce is of most importance. As shown in section 4.1.1, the desired velocity in the wind tunnel for the scale model can be found from equation 4.5

$$u_m = \frac{0.6 \text{ m}}{0.15 \text{ m}} 15.28 \text{ m s}^{-1} = 61.12 \text{ m s}^{-1}$$

Which in accordance to the range of The Red wind tunnel.

4.2 Equipment

The equipment required for performing a wind tunnel test can be seen below:

- The Red wind tunnel (60 m s^{-1} to 65 m s^{-1})
- 1/4 scale wing
- Syringe inserts
- Rubber tubing
- Pressure transducer

The instrumentation and the Red wind tunnel is described below, along with a thorough description of the scale wing designed and produced for the experiment.

4.2.1 Instrumentation

The Red Wind Tunnel

The red wind tunnel is an open loop wind tunnel located at DTU Lyngby. It measures $0.5\text{ m} \times 0.5\text{ m} \times 1.3\text{ m}$ in the test section, with a maximum wind speed of 65 m s^{-1} . The wind tunnel functions in low Reynolds number, which fits with the chosen MSHD aerofoil. The system employs a hot wire velocity probe.

FiXme Note: What'd we use to collect data?

4.2.2 Manufacturing the 1/4 Scale Rear Wing

The 1/4 scale rear wing was machined at Philips Lighting by Rasmus Himborg.

Blueprints

The wing requires a series of special holes for the measurements needed. 15 holes have to be made along the very narrow wing profile, in order to measure the pressure on the wing's surface. The pressure taps have to be 0.8 mm on the outside, with an inner bore hole with 1.2 mm, in order to have a syringe inserted. Secondly, the wing needs to be separated into smaller parts, as drilling pressure outlets through the entire wing is very difficult. Thus, the large wing is dissected into three parts. Two regular wings, and a central part with 15 pressure taps. The middle section contains the pressure outlets, where syringes serve as connectors to rubber pressure tubes, which has to be lead out through the center of the wings adjacent of the pressure-measuring wing. Furthermore, aligning the three wing sections has to be fairly accurate. The center wing thus carries threaded holes, and the adjacent wings have M4 holes where a threaded rod can pass through and be tightened. The final design of the centerpiece can be seen in figure 4.1.

Material selection is based on the ease of machinability - a CNC-miller was provided to us, along with ample amounts of aluminium. This scale wing is not to be used in the actual race car, so weight is not a concern. Construction the 1/4 scale wing is not completely trivial. High precision is required for the surface finish, and the pressure taps have to be small in diameter: 0.8 mm.

FiXme Note: maybe fix blueprint to be more sexy/english

FiXme Note: Why this wing design? answer: Just a first guess that can be compared with easily later.

4.3. Experimental Procedure

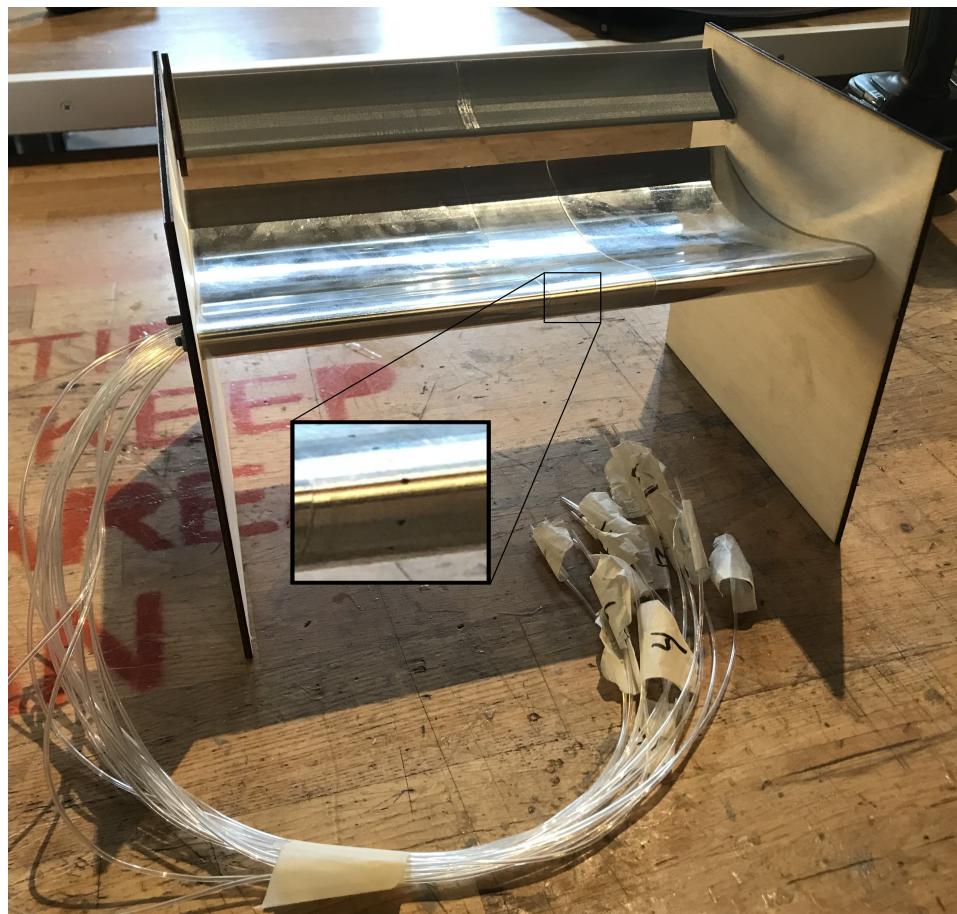

Figure 4.2: Down-scaled wing assembled with a zoom in on the pressure taps. The length of the entire wing is approximately 250 mm with a total chord length of 150 mm.

5

Simulation

The simulation will run in several parts. First, the wings relative placement between eachother will be optimized in a 2-dimensional environment. This involves, size, x - and y -distance between the multi-element wings, angle of attack and height relative to the chassis to give a good estimate of the wings placement range. Secondly, a 3-dimensional analysis of the entire wing with endplates will be performed. Endplate dimensions will be optimized, and further optimization of the height relative to the entire chassis to finalize the design and placement. Lastly, a complete computational solution to the entire car will finalize the aerodynamical package, and yield the total amount of drag and downforce.

5.1 Star-CCM+

5.2 Finite Volume method

Star-CCM+ employs the finite volume method, which will be covered briefly in this report.

5.3 Mesh Generation

The mesh has to be structured in accordance to best practice. Areas with high velocity and pressure gradients have to be dissolved in acceptable resolutions, in order to ensure correct results. Running an initial test on a generic mesh shows us where the wing requires greater resolution. Gradients are easily visible around the wing's leading edge, and generally around the solid bodies. Furthermore, aligning the mesh with the flow improves accuracy and rate of convergence. .

7

Discussion

8

Conclusion

bla

Perspective

The Eevee has to be rebuilt next year, and in order to help the effort along for future students, a list of potential upgrades are listed below, with estimates of how valuable each change is in regards to downforce/drag reduction gain.

8.1 Drag Reductive System

A drag reductive system (DRS) is well-known from Formula 1, and has in the recent years been gaining traction (or lack therof :)))) in the Formula Student. It is a natural extension to the aerodynamics of the car, as Formula Student has much less restrictions on aerodynamics than Formula 1. Automatically adaptive DRS, that measures the car's relative downforce and the angle of the steering column could give a big edge on straights, as flipping the wing up to reduce drag increases the top speed.

8.2 Slats, Flaps, Gills and Cutaway

<https://www.jmranalytical.com/single-post/2017/04/06/Rear-Wing-Investigation>

We already have a multi element wing, but increasing the amount of elements increases the amount of downforce we can pull out of the same design.

8.3 Suspension Integration

- Nice to have downforce directly on the wheels - Gives more unsprung mass though. That might be an issue.

Media

The project gained a lot of media attraction. For the interested reader, more can be found below.
